Logistic Regression and Binary Classification

Consider any logistic hypothesis $h(\mathbf{x}) = \frac{1}{1 + \exp(-\mathbf{w}^T \mathbf{x})}$ that approximates $P(y|\mathbf{x})$. 'Convert' $h(\mathbf{x})$ to a binary classification prediction by taking sign $(h(\mathbf{x}) - \frac{1}{2})$. What is the equivalent formula for the binary classification prediction?

- 2 sign $(\mathbf{w}^T \mathbf{x})$
- 3 sign $\left(\mathbf{w}^{\mathsf{T}}\mathbf{x} + \frac{1}{2}\right)$
- 4 none of the above

Reference Answer: (2)

When $\mathbf{w}^{\mathsf{T}}\mathbf{x} = 0$, $h(\mathbf{x})$ is exactly $\frac{1}{2}$. So thresholding $h(\mathbf{x})$ at $\frac{1}{2}$ is the same as thresholding $(\mathbf{w}^{\mathsf{T}}\mathbf{x})$ at 0.

$$E_{\text{in}}(\mathbf{w})$$

$$err(\mathbf{w}, \mathbf{x}, y) = ln(1 + exp(-y\mathbf{w}\mathbf{x}))$$
: **cross-entropy error**

Fun Time

The four statements below help us understand more about the cross-entropy error $err(\mathbf{w}, \mathbf{x}, y) = ln(1 + exp(-y\mathbf{w}^T\mathbf{x}))$. Which statement is not true?

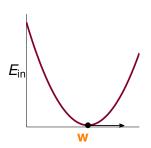

- 1 For any \mathbf{w}, \mathbf{x} , and y, $err(\mathbf{w}, \mathbf{x}, y) > 0$.
- **2** For any **w**, **x**, and y, $err(\mathbf{w}, \mathbf{x}, y) < 1126$.
- 3 When $y = \text{sign}(\mathbf{w}^T \mathbf{x}), \text{err}(\mathbf{w}, \mathbf{x}, y) < \ln 2$.
- 4 When $y \neq \text{sign}(\mathbf{w}^T\mathbf{x})$, $\text{err}(\mathbf{w}, \mathbf{x}, y) \geq \ln 2$.

Reference Answer: 2

1126, really? :-) You are highly encouraged to plot the curve of err with respect to some fixed y and some varying score $s = \mathbf{w}^T \mathbf{x}$ to know more about the error measure. After plotting, it is easy to see that err is not bounded above, and the other three choices are correct.

Minimizing $E_{in}(\mathbf{w})$

Consider the gradient $\nabla E_{\text{in}}(\mathbf{w}) = \frac{1}{N} \sum_{n=1}^{N} \theta \left(-y_n \mathbf{w}^T \mathbf{x}_n \right) \left(-y_n \mathbf{x}_n \right)$. That is, each example (\mathbf{x}_n, y_n) contributes to the gradient by an amount of $\theta \left(-y_n \mathbf{w}^T \mathbf{x}_n \right)$. For any given \mathbf{w} , which example contributes the most amount to the gradient?

- 1 the example with the smallest $y_n \mathbf{w}^T \mathbf{x}_n$ value
- 2 the example with the largest $y_n \mathbf{w}^T \mathbf{x}_n$ value
- 3 the example with the smallest $\mathbf{w}^T \mathbf{x}_n$ value
- 4 the example with the largest $\mathbf{w}^T \mathbf{x}_n$ value

Lecture 9: Linear Regression

Lecture 10: Logistic Regression

- Logistic Regression Problem
 P(+1|x) as target and θ(w^Tx) as hypotheses
- Logistic Regression Error cross-entropy (negative log likelihood)
- Gradient of Logistic Regression Error
 θ-weighted sum of data vectors
- Gradient Descent

roll downhill by $-\nabla E_{in}(\mathbf{w})$
